THE FINEST BEARINGS THAT CAN BE MADE

Barden's focus on super precision bearing technology has long been driven by the needs of our customers for greater accuracy, higher running speeds, longer life and a sensitivity to cost.

As a result, our entire R&D, design and manufacturing philosophy revolves around delivering innovative bearing solutions, better product reliability and lower system costs.

Meeting these stringent demands requires constant interaction with customers to learn more about their specific application requirements. Our own R&D efforts — along with our support of leading university mechanical engineering and metallurgical research projects — have laid the foundation for the development of new, ever more reliable precision bearing products.

While bearing tolerances are well-defined by DIN/ISO or ABEC standards, Barden super precision

bearings routinely exceed even these stringent guidelines, resulting in the production of the finest bearings that can be made.

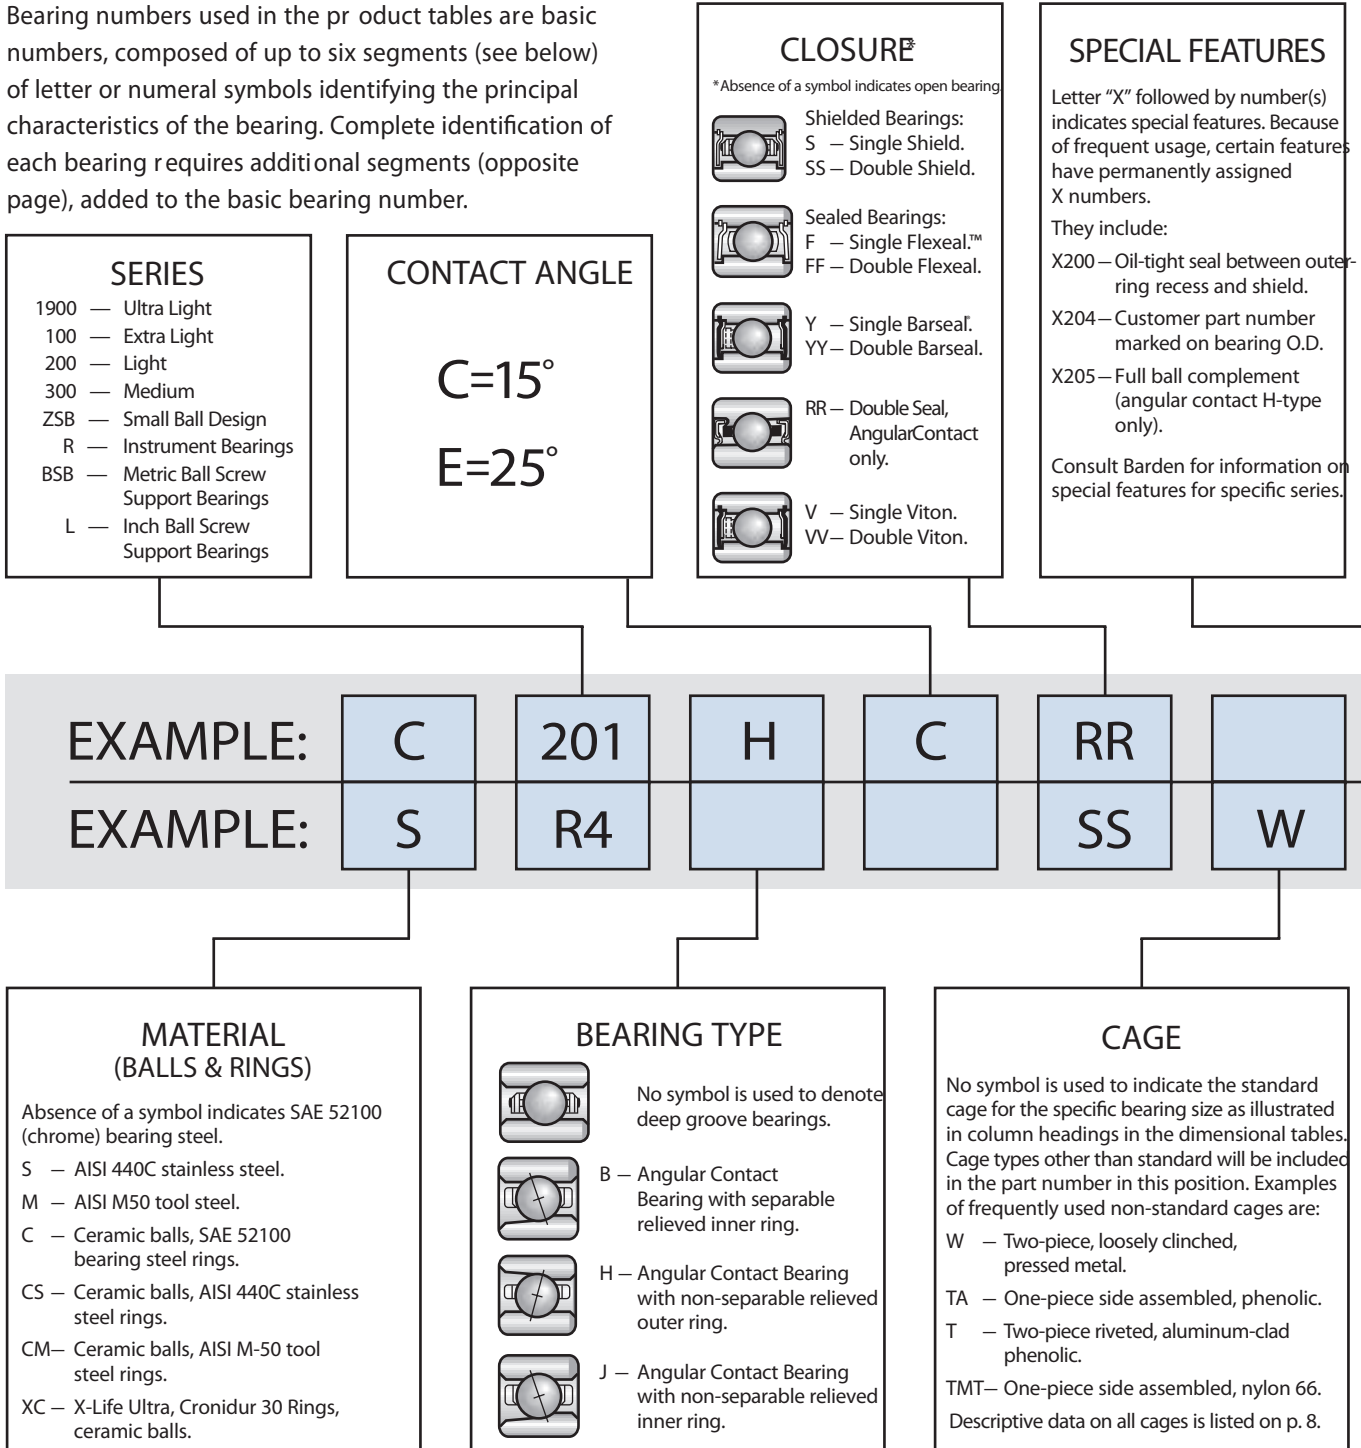

In addition to meeting — or exceeding — the demanding tolerance requirements of P4/ABEC 7 specifications, there are other Barden-imposed performance features not covered by these standards.

As a result, Barden super precision bearings set standards unchallenged by any other bearing manufacturer in the world today when it comes to performance reliability, greater accuracy, higher running speeds and longer life.

Barden's extensive product line means that whatever your application — from milling machines to textile winders to wood working machines — there's a precision bearing solution that's right for you.

NOMENCLATURE

Bearing numbers used in the product tables are basic numbers, composed of up to six segments (see below) of letter or numeral symbols identifying the principal characteristics of the bearing. Complete identification of each bearing requires additional segments (opposite page), added to the basic bearing number.

ABMA STANDARDS

Grades of precision have been set by the Annular Bearing Engineers Committee of the ABMA. Conventional ball bearings are manufactured to precision grades ABEC 1, ABEC 3, ABEC 5, ABEC 7 and ABEC 9 (highest). All Barden bearings in this catalog are produced to class ABEC 7 or

ABEC 9.

DUPLEXING

U – Single universal bearing. Any arrangement.
 DU– Set of two universal bearings.
 DB– Set of two bearings. Back-to-back arrangement.

DF – Set of two bearings. Face-to-face arrangement.

DT – Set of two bearings. Tandem arrangement.

PRELOAD

L=Light M=Medium H=Heavy

RADIAL RUNOUT

Only special radial runouts are shown in M & I bearing numbers and are identified by letter "E".

E – Radial runout less than standard tolerances. Consult Barden for details.
 When "E" is followed by letter "R", high point of eccentricity is marked on bearing according to the following code:

R – Inner ring marked for high point of eccentricity.
 R1 – Outer ring marked for high point of eccentricity.
 R2– Both inner and outer rings marked for high points of eccentricity.

LUBRICATION

Type of lubricant used is always indicated in bearing number on packaging. Letter "O" denotes oil, letter "G" denotes grease. Number codes following letters indicate type of lubricant. Lubricants frequently used are:

Oils
 O-9 – Exxon Aviation Instrument Oil
 O-11 – Winsorlube L-245X
 O-14 – Exxon 2389 Turbo Oil
 O-40 – Exxon Coray 100

Greases
 G-2 – Exxon Beacon 325
 G-18 – Nye Rheotemp 500
 G-33 – Mobil Grease #28
 G-42 – Nye Rheolube 350-SBG-2
 G-46 – Kluber ISOFLEX NBU-15
 G-73 – Arcanol L-55
 G-74 – Exxon Unirex N3
 G-75 – Arcanol L-75

RADIAL PLAY

Numeral indicates range of radial play for deep groove bearings. For angular contact bearings, no code is shown for standard contact angles.

Note: Radial play code number is preceded by letter "K" when previous section of bearing number ends in a number. Letter "K" functions only as a separating symbol to avoid confusion.

FUNCTIONAL TEST

Most miniature and instrument bearings are available with low torque characteristics. Variations in torque levels are designated by the following symbols:

V – Guaranteed low maximum torque level.
 VK – Very low starting torque.
 VM – Very low running torque.
 VT – Actual torque trace furnished with each VM level bearing.

Consult Barden for specific torque levels.

(Note: Prior designation for guaranteed very low maximum torque levels was L.)

CALIBRATION

Bearing with calibrated bore or O.D. is denoted by letter "C". Coding used is as follows:

C – Bore and O.D. tolerance range separated into increments of .0001" and group indicated on packaging.

CXO– Calibration of bore only.
 COX– Calibration of O.D. only.
 C44 – Grouping of .00005", bore and O.D.
 C40 – Bore only calibrated in groups of .000050".
 C04 – O.D. only calibrated in groups of .000050".

BEARING FEATURES

Types of Bearings

The three basic types of ball bearings offered in this catalog are Deep Groove, Angular Contact with Separable Inner Ring (B T types), and Angular Contact with Non-Separable Inner or Outer Rings (H and J T types).

Deep Groove Bearings

Deep groove bearings have full shoulders on both sides of the raceways of both inner and outer rings, with cages to separate the balls. The deep groove design permits the support of either radial or thrust loads. Because of this versatility they are preferred for many applications. Offered in many sizes, with a variety of cage types and in open, shielded, and sealed styles, they are the logical choice for first consideration.

Typical deep groove bearings, open and shielded.

Angular contact bearings. Non-separable type H on left; separable type B on right. Shown with standard phenolic cages.

Angular Contact Bearings

Angular contact bearings are ideally suited for high speed applications where both axial and radial loads are to be supported, and where system rigidity requires preloading. The design inherently limits thrust loads to one direction, and are generally used in pairs or sets. Radial load support is limited and occurs only when thrust loads are present or preload is used.

The non-separable (H type) angular contact design permits using a larger complement of balls than is possible in the same size deep groove bearing. For this reason it has greater capacity. It also has higher speeds because of the phenolic one-piece cage.

The separable (B type) angular contact bearing utilizes cages designed to retain the balls when the outer ring assembly (including cage and balls) is separated from the inner ring. This type of bearing has the same high speed capability as the H type non-separable angular contact bearing. The separable design has advantages for certain applications.

Separable bearings simplify assembly of units where bearings are located in blind holes. The separable feature also permits dynamic balancing of a rotating component with inner rings mounted in place, apart from the outer ring and housing.

Both separable and non-separable angular contact bearings utilize machined phenolic cages.

Ball Bearing Closures

Closures (shields and seals) serve essentially the same purpose but to varying degrees. Each type of closure:

- Excludes contamination.
- Helps retain lubricants.
- Protects the internal assembly of the bearing from damage during handling or assembly.

The availability of shields and seals is shown in the tables that follow.

All types of closures are assembled in the outer ring in a manner as to provide controlled radial positioning with minimum distortion of the ring.

Stainless Steel Shields

Shields are precision stamped of stainless steel to a

contoured configuration to provide strength and rigidity, resistance to vibration, and positive radial and axial positioning against the shield shoulder in the outer ring.

The shield does not contact the inner ring and thus does not affect bearing performance.

Flexeals

The Flexeal is a Barden-developed seal with superior high speed characteristics. A thin layer of inert fibrous material is permanently bonded to an aluminum washer, properly shaped by stamping, and positioned in the outer ring just as a shield. The fiber absorbs a proper amount of lubricant which is continuously fed to the ground seal wiping face on the inner ring notch. Positive Flexeal positioning provides a close control of seal wiping action, resulting in higher speed capability (compared with other seal designs) after run-in.

Flexeals are recommended in applications where contamination is generated around the bearing or in equipment which must operate in a contaminated environment.

Bearings with Flexeals are generally used at speeds where the dominant factors in torque are seal friction plus lubricant drag, which vary with type of lubricant, speed, and operating temperature. Flexeals may be used at temperatures up to 300°F. A maximum temperature of 350°F is acceptable for short periods. Total torque or power requirements are best determined by test in the application.

Barseals

The barseal is a molded rubber seal which incorporates a metal stiffening insert. This design provides maximum volume within the bearing for lubrication. Speed considerations limit their use to

grease-lubricated bearings with P or TMT cages. Effective outer ring sealing makes these seals preferred with outer ring rotation. Maximum operating temperature is 225°F.

Sealed Angular Contact Spindle Bearings

Sealed spindle bearings allow the use of a more economical grease lubrication system. These bearings are factory-filled with Barden's high-performance G-75 grease, then fitted with "non-contact" seals on both sides.

The advantages of Barden's sealed spindle bearings include:

- A non-contacting seal design.
- Greased for life lubrication.
- Box-to-spindle (ready for assembly).
- Interchangeable with standard spindle bearings.
- Proper grease quantity.
- Controlled greasing process.
- Elimination of contamination during handling.
- Enhanced performance due to added sealing and grease near contact zone especially in vertical applications.

BEARING FEATURES

Cages

Barden deep groove and angular contact bearings are available with different types of cages offering a choice of performance characteristics for a range of applications.

Deep Groove

Principal cage designs for deep groove bearings are the pressed stainless steel, one-piece snap type (Q), used in smaller sizes, and the two-piece ribbon style (P), used in larger sizes. The anti-windup cage (W), a Barden development, is available in many miniature and instrument sizes. It is a two-piece light-weight ribbon style designed to prevent cage windup in sensitive low torque applications. Phenolic high speed cages are one-piece snap style (TA) in smaller sizes, and two-piece riveted phenolic, reinforced with aluminum (T) in larger sizes.

Angular Contact

Outer ring land-guided phenolic cages, designed for endurance at high speeds, are used in both separable and non-separable angular contact bearings.

Separable Type B: Outer ring has full shoulders, inner ring has one shoulder cut away. Inner ring is removable for mounting on the shaft separately from the outer ring assembly.

Non-separable Type H: Inner ring has full shoulders, outer has one shoulder cut away with a small retaining lip at the edge of raceway.

Non-separable Type J: Outer ring has full shoulders, inner ring has one shoulder cut away with a small retaining lip at the edge of raceway.

Other cages are available, but should not be specified without consultation with Barden Product Engineering.

CAGES FOR DEEP GROOVE BEARINGS				
Type	Cross Section	Illustration	Use	Material
Q – Crown type, snap cage			General purpose	Stainless steel AISI 410
P – 2-piece ribbon cage, full clinch			General purpose	Stainless steel AISI 430 AISI 305
W – 2-piece ribbon cage, loosely clinched			General purpose, low torque instruments	Stainless steel AISI 430 AISI 305
TA – Crown type, snap cage			High speed, general purpose	Phenolic
T – 2-piece riveted			High speed, general purpose	Phenolic Aluminum Clad
TMT – Crown type, snap cage			General purpose	Filled nylon 66
TB – Crown type, snap cage			Light load, no lubrication, in stainless steel bearing only, high and low temp., moderate speed	BarTemp
TQ – Crown type, snap cage			High speed, quiet operation	Delrin*

CAGES FOR ANGULAR CONTACT BEARINGS				
Type	Cross Section	Illustration	Use	Material
B [†] – 1-piece, for bearings with separable inner rings			High speed, general purpose	Phenolic
H [†] – 1-piece, for bearings with non-separable outer rings			High speed, general purpose	Phenolic
J [†] – 1-piece, for bearings with non-separable inner rings			High speed, general purpose	Phenolic

* Reg. DuPont Trademark.

† Symbol for bearing type. No symbol is used in nomenclature for standard cage.

Preloading

Preloading is the removal of internal clearance by placing a permanent thrust load on the bearings. Preloading is used to satisfy one or more of the following requirements:

1. Elimination of all radial and end play.
2. Increased rigidity of a system.
3. Reduction of non-repetitive runout.
4. Limitation of change in contact angle between inner and outer ring at very high speed.
5. Prevention of ball skidding under very high acceleration.

Bearings should not be preloaded more than is necessary to obtain the desired rigidity. Excessive preloads generate heat which reduces speed capability and bearing life. Two basic methods of achieving preload are:

1. Use of universal duplexed bearings (DU).
2. Spring preloading.

Different types of spring preloading.

Typical spring members used for preloading

Coil spring

Spring washers

Wave

Belleville

Finger

Spring Preloading

This is the simplest way to preload bearings. It should be considered first, and used if all application requirements can be met. Most assemblies which do not require specific yield characteristics can be successfully spring preloaded.

Spring preloading offers several advantages. With properly selected springs, it can be more constant than other systems. It is generally less sensitive to differential expansion, and offers more accommodation to minor misalignment. It also allows greater speeds than in rigidly preloaded systems.

Springs may be of many types — wavy washers, belleville washers, coil springs, spring block, etc.

Rigid Preloading

To achieve, solid preload must be carried out with great care using highly accurate parts for the adjustment. Threaded members with spacers and precision shims are typical means of providing axial adjustment for preload. Lapped shims made to fine gradations of thickness are usually preferred since screw threads can produce misalignment effects.

Care must be taken in the mounting, design and installation procedures to avoid excessive preload due to thermal changes that can develop between assembly at room temperature and operating temperature.

The speed reduction factors shown on page 12 must be used with a rigidly preloaded system.

Duplexed Bearings

Angular Contact

Duplexed bearings are made by relieving selected faces of inner and outer rings by an amount called the preload offset. When the bearings are clamped into position, the offset faces are brought together, introducing a preload into the bearing system.

Fig. 1: DB mounting before clamping.

Fig. 2: DB mounting after clamping.

DB (back to back)

Preload offsets of abutting faces of inner rings causing contact angle lines of a pair of bearings to converge toward the outside diameter of the bearings. Bearings are mounted with marked faces or full shoulder side of outer rings together. Marked faces of outer rings and narrow faces of inner rings are mounted on separable (B) type bearings.

Control of the preload is achieved by controlling the amount of preload offset. All Barden angular contact duplexed bearings are universally ground (DU), thus enabling them to be mounted in any of the three basic duplexing configurations.

High points of eccentricity are marked (asterisks) on inner rings of duplexed angular contact bearings to reduce assembly errors.

This mounting method is preferred for applications where high moment rigidity is required. DB mounting is also preferred where the shaft runs warmer than the housing, a common operating condition. Consequently, higher operating speeds are possible.

A Duplex DB pair before preloading (Fig. 1) has inner rings with a controlled preload offset. When inner rings are clamped together on the shaft (Fig. 2) the specified preload is established within the pair.

DF (face to face)

Preload offsets of abutting faces of the outer rings causing lines of contact of a pair of bearings to converge toward the bearing bores. Mounted with unmarked or relieved faces of outer rings together. Unmarked faces of outer rings and wide faces of inner rings are mounted together on separable (B) type bearings.

The DF mounting is preferred in slow speed applications where shaft binding due to misalignment will be encountered.

The DF pair before preloading (Fig. 3) has outer rings with controlled preload offset. When outer rings are clamped together in housing (Fig. 4) the specified preload is established within the pair of bearings.

Fig. 3: DF mounting before clamping.

Fig. 4: DF mounting after clamping.

DT (tandem)

Preload offsets of abutting faces of both inner and outer rings create parallel lines of contact. Mounted with marked or full shoulder side of outer ring of one bearing

Fig. 5: DT mounting before preloading.

Fig. 6: DT mounting after preloading.

against unmarked or relieved face of outer ring of other bearing. DT pairs offer greater capacity without increasing bearing size, through load sharing. Additionally, they can be used to achieve a significant increase in axial and radial rigidity.

Duplex DT tandem pair before preloading (Fig. 5) has inner and outer rings with equalized offsets. When mounted and thrust loaded (Fig. 6), loads are shared equally by both bearings.

Duplex DT tandem pair before preloading (Fig. 5) has inner and outer rings with equalized offsets. When mounted and thrust loaded (Fig. 6), loads are shared equally by both bearings.

Deep Groove

Deep groove bearings may also be duplexed and must be ordered as such. The mounting arrangements differ from angular contact bearings in that marked faces are outboard for DB mounting and inboard for DF mounting. Shields and seals are always installed on only the outboard sides of both rings.

Spacers

All duplexed bearings can be separated by equal width spacers (Fig. 7) to increase moment rigidity. Inner and outer ring spacer widths (axial length) must be matched to within 0.001 mm, and faces must be square, flat and parallel within 0.001 mm to preserve preload and alignment.

Fig. 7: Duplex bearing pairs with equal width spacers.

TECHNICAL INFORMATION

Radial Play

Deep Groove Bearings

Radial play is the measured clearance in the radial direction of an assembled bearing. Its magnitude is an important factor in bearing performance. Without radial play, interference fits and normal expansion of components cannot be accommodated, causing binding and early failure. High speeds create heat through friction and require greater than normal radial play. If thrust loads predominate, higher radial play will tend to increase load capacity, life, and axial rigidity. Low radial play codes are better suited for slow speed radially supported applications.

Deep groove bearings are available in a range of radial play groups. Each radial play code, represents limits to the range of internal clearance. Code 3 and Code 5 bearings are more readily available than those with other radial play codes.

RADIAL PLAY — DEEP GROOVE BEARINGS			
Bearing Sizes	Code 3	Code 5	Code 6
34 – 39, 100 – 103	.0002" to .0004"	.0005" to .0008"	.0008" to .0011"
R0 – 10, R133 – R1810	.0002" to .0004"	.0005" to .0008"	.0008" to .0011"
104 – 107, 200 – 205	.0002" to .0005"	.0005" to .0009"	.0009" to .0014"
108, 206 – 209	.0002" to .0005"	.0007" to .0012"	.0012" to .0017"
109 – 110, 210	.0004" to .0008"	.0008" to .0013"	.0013" to .0019"

(ABMA Designation)	0	3	4

Angular Contact Bearings

Radial play, when combined with thrust loading, creates a line of contact between the ball and both races. The angle made by this line and a plane through the ball centers is called the contact angle. Standard spindle size angular contact bearings are assembled with a radial play that provides either a nominal 15° (C) or 25° (E) contact angle. The 15° contact angle bearing is standard for the 100H, 200H, and 300H series and provides the optimum combination of both axial and radial capacity and rigidity. Where greater axial rigidity is required, the 25° contact angle (100HE and 200HE series) is preferred. Where extreme axial rigidity is necessary, a 60° contact angle series is also available. Refer to the section on ball screw support bearings, page 24.

Limiting Speeds

Spindle Bearings

Limiting speeds given in the product tables represent maximum values under ideal conditions, namely light spring loads, adequate lubrication, and proper installation and alignment. When less than ideal conditions exist, speeds should be limited to lower values. Factors for calculating the speed limits of rigidly preloaded bearing systems are given below.

SPEED REDUCTION ($n^* \cdot f_r$) FOR SPINDLE BEARING SETS				
Bearing Arrangement	Factor f Bearing Preload			
	L	M	H	
Large bearing distance				
	0.85	0.75	0.50	
	0.80	0.70	0.50	
	0.75	0.65	0.45	
Locating bearing		Floating bearing		
	0.75	0.60	0.35	
	0.65	0.50	0.30	
	0.65	0.50	0.30	
	0.72	0.57	0.37	

Lubricants

Lubricants for typical applications are listed below.

Barden Code ⁶	Designation	Temperature	Limiting dN Value [†]
	OILS		
0-9	Exxon Avia. Instrument Oil	-65°F to +150°F	1.5× 10 ⁶
0-11	Winsorlube L-245X	-67°F to +175°F	1.5× 10 ⁶
0-14	Exxon 2389 Turbo Oil	-65°F to +350°F	1.5× 10 ⁶
	GREASES		
G-2	Exxon Beacon 325	-65°F to +250°F	.40× 10 ⁶
G-4	Nye Rheolube 757 SSG	-40°F to +200°F	.65× 10 ⁶
G-12	Chevron SRI-2	-20°F to +300°F	0.4× 10 ⁶
G-18	Nye Rheotemp 500	-50°F to +350°F	0.5× 10 ⁶
G-33	Mobil #28	-80°F to +350°F	0.4× 10 ⁶
G-42	Nye Rheolube 350-SBG-2	-30°F to +250°F	.65× 10 ⁶
G-46	Kluber Isoflex NBU-15	-40°F to +250°F	.75× 10 ⁶
G-74	Exxon Unirex N3	-40°F to +300°F	.65× 10 ⁶
G-75	Arcanol L-75	-60°F to +250°F	1.2× 10 ⁶

* See Bearing Numbering System pages 4 – 5.

† dN = bearing bore in mm (or inches × 25.4) × speed in RPM.

Although greases will operate at maximum temperature and speeds indicated, grease life will be limited. Significantly greater grease life will be obtained at lower speeds and lower temperatures.

Bearings are furnished with the following standard lubricants:

Bearing Types	Lubricant Codes
All deep groove, open bearings — instrument	0-11
All deep groove, open bearings — spindle	0-9
All shielded or sealed bearings — instrument	G-2
All shielded or sealed bearings — spindle	G-74
All angular contact bearings — instrument	0-11
All angular contact bearings — spindle	0-11
All sealed angular contact bearings — spindle	G-75
All ball screw support bearings	G-73

Tolerances

Barden precision ball bearings are manufactured to standard grades of precision which establish tolerances for size and geometric accuracy. These standards are set by the Annular Bearing Engineers Committee (ABEC) of the Anti-Friction Bearing Manufacturers Association, Inc. (ABMA). These same standards have been accepted by the American National Standards Institute, Inc. (ANSI) and, through international

agreements, conform essentially with standards for precision ball bearings developed by the International Organization for Standardization (ISO).

Barden manufactures spindle and turbine bearings to class ABEC 9 and instrument bearings to class ABEC 7P.

Handling Bearings

All Barden bearings are manufactured, assembled, inspected and packaged in a strictly controlled environment.

If the quality and high performance potential built into precision bearings is to be realized by the bearing user, the same degree of care and cleanliness should be used in handling and installing the bearings.

Achievement of the required degree of cleanliness requires that all work spaces, tools, transport equipment, fixtures and the parts mated to the bearings be clean. Anyone handling bearings should recognize the need for careful handling and cleanliness.

Guidelines for Handling Bearings

- Keep bearings in their original packaging until installation.
- Barden bearings are demagnetized prior to shipment. If there is any indication that bearings have become magnetized, which would attract contaminants, the wrapped bearings should be passed through a demagnetizer.
- Do not wash new bearings. Open bearings are lubricated with a petroleum-base oil which is compatible with oil mist lubricating systems and most spindle bearing greases. Sealed and shielded bearings are grease lubricated.
- Wear non-shedding, clean finger coverings, like plastic gloves or use tweezers when handling bearings.
- Use clean, burr-free tools, not painted or chrome-plated.
- Transmittal of forces through the bearing must be prevented to avoid brinelling which can damage bearings. Apply force only to the ring being fitted.
- Do not hammer. Use an arbor press or induction heater.
- Make sure outer rings are free to float for shaft expansion (if design requires a floating bearing arrangement).
- If it is ever necessary to open the packaged bearing except for installation, it should be stored in a clean, covered container with proper identification prior to installation. The full nomenclature will appear only on the original package.

CERAMIC HYBRIDS AND X-LIFE ULTRA BEARINGS

Ceramic Hybrids

Use of ceramic (silicon nitride) balls in place of steel balls can radically improve bearing performance several ways. Because ceramic balls are 50% lighter than steel balls, and because their surface finish is almost perfectly smooth, they exhibit vibration levels two to seven times lower than conventional steel ball bearings.

Ceramic hybrid bearings also run at significantly lower operating temperatures, and can allow running

Ceramic Ball Bearing Features

60% lighter than steel balls

- Centrifugal forces reduced
- Lower vibration levels
- Less heat build up
- Reduced ball skidding
- Fatigue life increased

50% higher modulus of elasticity

- Improved spindle rigidity
- Naturally fatigue resistant

Tribochemically inert

- Low adhesive wear
- Improved lubricant life
- Superior corrosion resistance

Benefits of Ceramic Ball Bearings

- Bearing service life is two to five times longer, five to ten times longer with X-Life
- Running speeds up to 50% higher
- Overall accuracy and quality improves
- Better workpiece finish characteristics
- Lower operating costs
- Increased productivity
- High temperature capability
- Cutting tool life is increased
- Electrically non-conductive

speeds to increase by as much as 40% to 50%.

Bearings with ceramic balls have been proven to last up to five times longer than conventional steel ball bearings. Lower operating temperatures help extend lubricant life.

Spindles equipped with ceramic hybrids show higher rigidity and higher natural frequency making them less sensitive to vibration. Improved stability leads to greater accuracy, better workpiece finish characteristics, lower scrap rates and reduced downtime. Diamond cutting tool life can also be prolonged.

Because of the unique properties of silicon nitride, ceramic balls drastically reduce the predominant cause of surface wear in conventional bearings (metal rings/metal balls). In conventional bearings, microscopic surface asperities on balls and races will “cold weld” or

COMPARISON OF BEARING STEEL & SILICON NITRIDE PROPERTIES		
Property	Steel	Ceramic
Density (g/cm ³)	7.8	3.2
Elastic Modulus (10 ⁶ psi)	30	45
Hardness	R _c 60	R _c 78
Coefficient of thermal expansion (X10 ⁻⁶ /°F)	6.7	1.7
Coefficient of friction	0.42 dry	0.17 dry
Poisson's ratio	0.3	0.26
Maximum use temperature (°F)	620	2000
Chemically inert	No	Yes
Electrically non-conductive	No	Yes
Non-magnetic	No	Yes

Ceramic balls are lighter and harder than steel balls, characteristics which improve overall bearing performance.

stick together even under normal lubrication and load conditions. As the bearing rotates, the microscopic cold welds break, producing roughness and, eventually, worn contact surfaces. This characteristic is known as adhesive wear. Since ceramic balls will not cold weld to steel rings, wear is dramatically reduced. Because wear particles generated by adhesive wear are not present in ceramic hybrids, lubricant life is also prolonged. The savings in reduced maintenance costs alone can be significant.

X-Life Ultra Bearings

X-Life Ultra bearings were developed for the highest demands with respect to speed and loading capability. These bearings are hybrid ceramic bearings with bearing rings made from Cronidur 30, a high nitrogen, corrosion resistant steel. Cronidur 30 shows a much finer grain structure compared with the conventional bearing steel 100Cr6 (SAE 52100) resulting in cooler running and higher permissible contact stresses. Basically all bearing types are available as X-Life Ultra bearings.

The longer service life of X-Life Ultra bearings when compared to conventional bearings also contributes to an overall reduction in the total system costs. When calculating the indirect costs of frequent bearing replacement — which include not just inventory, but machine downtime, lost productivity and labor — the cost savings potential of X-Life Ultra bearings become significant.

A comparison of 440C carbides and Cronidur carbonitrides shows that Cronidur has a much more homogeneous grain structure.

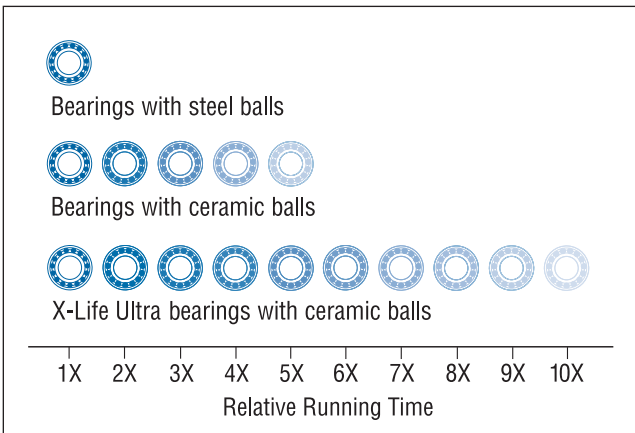

Lower operating temperature. As running speeds increase, ceramic balls always run cooler than conventional steel balls. With reduced heat build up, lubricant life is prolonged.

Running speed of ceramic ball exceeds same-size steel ball by 40%. Converting to an X-Life Ultra bearing with ceramic ball will boost running speeds an additional 25%.

Deviation from true circularity (DFTC). Polar trace of a 5/8" silicon nitride ball indicates near perfect roundness, which results in dramatically lower vibration levels.

Relative useful life of steel, ceramic hybrid and X-Life Ultra bearings with ceramic balls.

Dynamic stiffness analysis shows better rigidity and higher natural frequency for hybrid bearings.

• Also available in AISI 440C stainless steel. To order, add prefix "S" to the basic bearing number.

Detail close-up showing how Flexeal Seals provide sealing action. If it is necessary to use a single Flexeal, indicate by using a single suffix "F" in the bearing number.

SERIES ZSB/ SMALL BALL, HIGH SPEED

Design

Barden engineers have developed the ZSB small ball angular contact sealed series spindle bearings to allow machine tools to operate at higher running speeds (up to 20% more) while maintaining optimum workpiece finish characteristics. The small ball feature of the ZSB series allows a greater number of balls to be used, increasing bearing stiffness, which leads to improved machining accuracy at higher speeds.

Barden's ZSB series are angular contact ball bearings that offer optional integral seals which reduce the chances of bearing failure through contamination and prolong lubricant life when bearings are grease lubricated. Seals are available as an option on most sizes. Check for availability.

The inner ring outside diameter land is removed from one side and the outer ring bore diameter land is removed from the opposite side. This allows for optimum exposure and flow through characteristics for air/oil lube systems.

Contact Angles: Standard contact angle is 15°. In the small ball product line Barden offers 25° bearings for high speeds which are preferred for many of the newer high speed applications.

In many machine tool spindle bearing applications at higher speeds the advanced design of the Barden 25° bearing will function at speeds more like a 15° bearing. The inner ring expands from centrifugal forces and reduces the radial clearance. As a result, the contact angle decreases in operation. Add to this the effect of the inner ring temperature being hotter than the outer ring and you have the operating contact angle of many high speed 25° bearings operating over one million dN.

Preload increase at the higher speeds is always a problem with high speed spindles due to the heat generation when solid preloading is used. Therefore, another major advantage of the 25° contact angle is a much lower preload increase at high speeds when compared to the 15° bearing, due to the favorable internal geometry.

Bearing Data: Bearing data applicable to these bearings is shown in the following tables. Lubrication and mounting data can be found in the Engineering section.

Cages: Standard cage is a one-piece phenolic type (no symbol) with circular ball pockets.

Attainable Speeds: Limits given are for spring preloaded single bearings.

Material: Standard material is SAE 52100 bearing steel for both rings and balls. With the option of using silicon nitride ceramic balls even higher speeds can be attained. Bearings also available in X-Life Ultra design (XCZSB).

Duplexing: All bearings are available universally ground (DU) for DB, DF, or DT mounting in sets of two or more. Bearings may also be ordered in specific DB or DF duplex pairs. Standard light, medium and heavy preloads are shown in the following product tables.

Lubricant: Desired lubrication should be specified when ordering, based on speed and temperature conditions of the application.

Calibration: For applications that cannot tolerate extreme fits, selective fitting with calibrated parts should be considered. Selective fitting utilizes a system of sizing bearings, shafts and housings within the diametral tolerance range and selectively assembling those parts which fall within the same respective area of the range. When Barden bearings are calibrated, they are sorted into groups and are specified by calibration code.

All ZSB Series Bearings also available with 25° contact angle, ceramic balls and X-Life Ultra (Cronidur) rings.

BALL SCREW SUPPORT BEARINGS — SERIES L, BSB, AND 7602/7603 SERIES

Design/Applications

Barden Series L (inch), BSB (metric), and 7602/7603 (metric) ball screw support bearings are manufactured specifically for high performance ball screw applications, where extreme rigidity requirements preclude the use of standard angular contact bearings. The internal configuration has been designed to provide an optimum combination of high rigidity, low drag torque, exceptional control of axial runout, higher running speeds and longer life.

All Barden ball screw support bearings are non-separable angular contact bearings and have cutaway shoulders on both the inner and outer rings. They can support very high thrust loads in one direction or combinations of radial and thrust loads, but not radial loading alone. These bearings are designed to provide machine tool drive systems with extreme axial rigidity, low drag torque and minimal axial runout. They are intended for specific applications in machine tools, e.g., ball screw supports, cross slides, X-Y table positioners and transfer tables. They should not be used in place of standard angular contact spindle bearings.

These bearings are available in standard duplex or quadruplex sets. In addition, we will supply custom combination sets to meet specialized application needs.

Limiting Speeds

Limiting speeds shown on page 25 are useful guidelines. Actual speed limits must be based on application characteristics. Life requirements, heat transfer conditions, loading and lubrication methods are typical influential factors.

Preloads

Standard values (heavy) shown in table will be supplied unless otherwise specified. Barden recognizes that some applications do not require the full axial stiffness (compliance) of the standard preload and will supply bearings with custom-ground preloads if required.

Cages

All metric series bearings have a molded nylon, glass fiber reinforced polyamide cage with spherical ball pockets. Series L bearings have a land-piloted cage of reinforced phenolic, precision-machined, with evenly spaced ball pockets.

Seals

Some ball screw support bearings may also be available in sealed versions. Ask your Barden sales engineer for details.

Mounting and Fitting

Normal fitting practice is line-to-line to loose for both shaft and housing fits, as shown in table at right.

All bearing pairs and sets are match-marked on their outside diameter surfaces to indicate correct positioning of each bearing. Barden packaging also contains detailed instructions for proper installation.

Recommendations for shaft and housing shoulder diameters are based on maximum support of duplex-mounted bearings. In circumstances with other mounting arrangements, consult Barden Product Engineering.

Life Calculations

Most ball screw support bearing applications are subject to duty-cycle loading with constantly changing feeds, speeds and operating loads. These factors, in combination with the heavy preloads built into the bearings, make L-10 life calculations irrelevant. Consult Barden Product Engineering for information which can be used in specific cases.

Materials

All ball screw support bearings (rings and balls) are made from 52100 steel. Bearings are also available with X-life Ultra rings and ceramic (silicon nitride) balls for even greater speeds and longer life.

Configurations: Standard configuration includes a cage; some sizes are also available in a full complement version (X205 suffix). Please consult Barden.

Maximum Shaft/Housing Fillet Radius Which Bearing Corner Will Clear: .040" (1.00 mm).

Attainable Speeds: Limits given are for DU mounted sets with standard heavy preload.

Material: SAE 52100 bearing steel is standard.

Duplexing: All bearings are universally ground D and can be mounted DU (Universal), DF (Face-to-Face), or DB (Back-to-Back), in pairs or in various combinations — three, four or more bearings as required. Standard preloads for pairs are shown. For quads (QUH), multiply the duplex preload indicated by two.

Tolerances: Standard precision class for all ball screw support bearings is ABEC 7, except for a tighter maximum raceway runout with side .0001" (2.5 µm).

Lubricant: Desired lubrication should be specified when ordering, based on torque, speed and temperature conditions of the application. Barden strongly recommends G-73 (L55), a NLGI Class 2 grease with EP additives. Consult Barden for details.

DOUBLE DIRECTION ANGULAR CONTACT THRUST BALL BEARINGS

Double direction angular contact thrust ball bearings are designed for use in machine tool spindles, in combination with cylindrical roller bearings. They are manufactured to precision tolerances. Double direction angular contact thrust ball bearings are designed to carry only thrust loads. They match the mounting dimensions of the NN30 Series double row cylindrical roller bearings.

External Dimensions

Double direction angular contact thrust ball bearings are designed to be mounted in conjunction with a double row radial cylindrical roller bearing (see pages 28-29). The nominal size of the external diameter is the same for both bearings which simplifies the machining of the housing bore. The external diameter tolerance of the double direction angular contact thrust ball bearing is designed so that there is clearance between the bearing O.D. and the housing bore. Use of this bearing type, in combination with a double row cylindrical roller bearing, offers the advantage of supporting both axial and radial forces separately.

Bearing Design

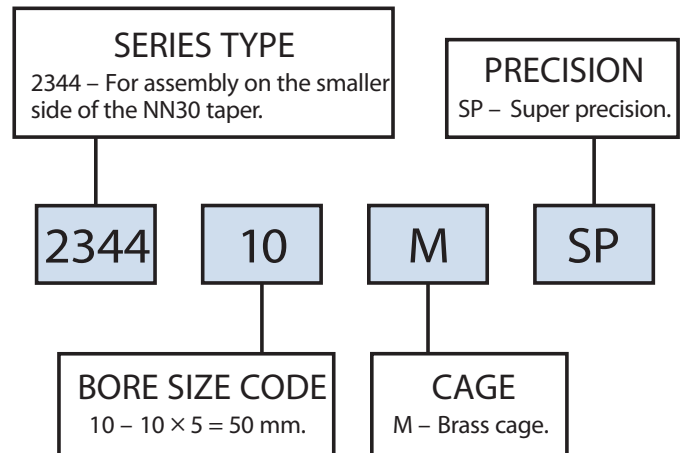

Double direction angular contact thrust ball bearings have a contact angle of 60° and are axially preloaded. The contact angle and the axial preload ensures good ball control, especially under the centrifugal forces with fast rotating spindles. These bearings are designed to accommodate high thrust loads. They have solid one piece machined brass cages which are ball guided.

This illustration of a milling spindle shows typical placement of a double direction angular contact thrust ball bearing used in combination with a double row cylindrical roller bearing in the workhead. The drive end of the spindle features one double row cylindrical bearing. This combination allows the spindle to operate with high rigidity at speed, while accommodating both axial and radial loads.

Bearing Nomenclature

Example: 234410M.SP

Speedability

Double direction angular contact thrust ball bearings are ideally suited for low to medium speeds. Speed limit values for grease and oil lubrication are given in the bearing table on page 31.

Lubrication

Double direction angular contact thrust ball bearings can be lubricated with either grease or oil. The outer ring O.D. has a lubricating groove in the center with lubricating holes. The application of the lubricant between the two rows of balls allows optimal distribution of lubricant to both raceways.

Rigidity

For optimum performance, machine tool spindle bearings must exhibit high rigidity as well as high precision. This means that they must run precisely and must allow only slight deflection under load. The double direction angular contact thrust ball bearings achieve high rigidity through their internal design with steep contact angle and internal defined heavy preload.

Bearing Mounting and Fitting

Mounting & Fitting

After a bearing selection has been made, the product or system designer should pay careful attention to details of bearing mounting and fitting.

Bearing seats on shafts and housings must be accurately machined, and should match the bearing ring

Values in inches.

Bearing Mounting and Fitting

Shaft & Housing Fits

The ideal mounting for a precision bearing has a line-to-line fit, both on the shaft and in the housing. Such an idealized fit has no interference or looseness.

As a practical matter, many influencing factors have to be considered:

- Operating conditions such as load, speed, temperature.
- Provision for axial expansion.
- Ease of assembly and disassembly.
- Requirements for rigidity and rotational accuracy.
- Machining tolerances.

Thus, the appropriate fit may have moderate interference, moderate looseness or even a transitional nature, as governed by operating requirements and the mounting design. Tables 5 and 6 provide general guidelines for typical applications, according to dominant requirements.

Fitting Practice

Interference fits (press fits) may be required when there is:

- A need to avoid mass center shifts.
- Heavy radial loading.
- Vibration that could cause fretting and wear.
- A need for heat transfer.
- A lack of axial clamping.
- To compensate for centrifugal growth of inner ring.

Interference fits should be used cautiously, as they can distort the raceway and reduce radial play. In preloaded pairs, reduction of radial play increases the preload. If excessive, this can result in markedly reduced speed capability, higher operating temperature and premature failure.

Loose fits may be advisable when:

- There are axial clamping forces.
- Ease of assembly is important.
- There must be axial movement to accommodate spring loading or thermal movements.

Table 5: Shaft/housing fits for miniature & instrument bearings.

	Dominant Requirements*	Fit Extremes, inches**		
		Random Fitting	Selective Fitting	
Shaft Fits	Inner ring clamped	Normal accuracy.	.0000 -.0004	-.0001 -.0003
		Very low runout, high radial rigidity.	+.0001 -.0003	.0000 -.0002
	Inner ring not clamped	Normal accuracy.	+.0001 -.0003	.0000 -.0002
		Very low runout, high radial rigidity.	+.0003 -.0001	+.0002 .0000
		Very high speed service.	+.0002 -.0002	+.0001 -.0001
		Inner ring must float to allow for expansion.	.0000 -.0004	-.0001 -.0003
		Inner ring must hold fast to rotating shaft.	+.0003 -.0001	+.0002 .0000
Housing Fits	Normal accuracy, low to high speeds. Outer ring can move readily in housing for expansion.	.0000 -.0004	-.0001 -.0003	
	Very low runout, high radial rigidity. Outer ring need not move readily to allow for expansion.	+.0001 -.0003	.0000 -.0002	
	Heavy radial load. Outer ring rotates.	+.0001 -.0003	.0000 -.0002	
	Outer ring must hold fast to rotating housing. Outer ring not clamped.	+.0004 .0000	+.0003 +.0001	

*Radial loads are assumed to be stationary with respect to rotating ring.

**Interference fits are positive (+) and loose fits negative (-) for use in shaft and housing size determination, page 35.

Bearing Mounting and Fitting

Loose fits for stationary rings can be a problem if there is a dominant rotating radial load (usually unbalanced). While axial clamping, tighter fits and anti-rotation devices can help, a better solution is good dynamic balancing of rotating mass.

The appropriate fit may also vary, as governed by operating requirements and mounting design. To ensure a proper fit, assemble only clean, burr-free parts. Even small amounts of dirt on the shaft or housing can cause severe bearing misalignment problems.

When press fitting bearings onto a shaft, force should be applied evenly and only to the ring being fitted or internal damage to the bearing — such as

brinelling — could result. If mounting of bearings remains difficult, selective fitting practices should be considered. Selective fitting — utilizing a system of bearing calibration — allows better matching of bearing, shaft and housing tolerances, and can provide more control over assembly.

Fitting Notes:

1. Before establishing tight interference fits, consider their effect on radial internal clearance and bearing preloads (if present). Also realize that inaccuracies in shaft or housing geometry may be transferred to the bearings through interference fits.

Table 6: Shaft and housing fits for spindle and turbine bearings.

	Dominant Requirements*		Fit Extremes, inches**			
			Nominal Bore Diameter, mm			
			7–30	31–80	81–180	
Shaft Fits	Inner ring clamped	Very low runout, high radial rigidity.	+ .0002 – .0001	+ .0003 – .0001	+ .0004 – .0002	
		Low to high speeds, low to moderate radial loads.	+ .00015 – .00015	+ .0002 – .0002	+ .0003 – .0003	
		Heavy radial load	Inner ring rotates	+ .0003 .0000	+ .0004 .0000	+ .0006 .0000
			Outer ring rotates	.0000 – .0003	+ .0001 – .0003	+ .0001 – .0005
	Inner ring not clamped	Very low runout, high radial rigidity, light to moderate radial loads.	+ .0003 .0000	+ .0004 .0000	+ .0006 .0000	
		Heavy radial load	Inner ring rotates	+ .0004 + .0001	+ .0005 + .0001	+ .0007 + .0001
			Outer ring rotates	.0000 – .0003	+ .0001 – .0003	+ .0001 – .0005
		Inner ring must float to allow for expansion, low speed only.	.0000 – .0003	– .0001 – .0005	– .0008 – .0002	
				Nominal Outside Diameter, mm		
				18–80	81–120	121–250
Housing Fits	Normal accuracy, low to high speeds, moderate temperature.		.0000 – .0004	+ .0001 – .0005	+ .0002 – .0006	
	Very low runout, high radial rigidity. Outer ring need not move readily to allow for expansion.		+ .0001 – .0003	+ .0002 – .0004	+ .0002 – .0006	
	High temperature, moderate to high speed. Outer ring can move readily to allow for expansion.		– .0001 – .0005	– .0001 – .0007	– .0002 – .0010	
	Heavy radial load, outer ring rotates.		+ .0004 .0000	+ .0006 .0000	+ .0008 .0000	

*Radial loads are assumed to be stationary with respect to rotating ring.

**Interference fits are positive (+) and loose fits negative (–) for use in shaft and housing size determination, page 35.

ENGINEERING

Bearing Mounting and Fitting

2. Radial internal clearance is reduced by up to 80% of an interference fit. Thus, an interference of .00025" could cause an estimated .0002" decrease in internal clearance. Bearings with Code 3 radial play or less should have little or no interference fitting.
3. Keep in mind that mounting fits may be substantially altered at operating temperatures due to differential expansion of components. Excessive thermal expansion can quickly cause bearing failure if the radial play is reduced to zero or less, creating a radial preload.
4. An axially floating loose fit for one bearing of two-bearing system is usually needed to avoid preloading caused by thermal expansion during operation.
5. When an interference fit is used, it is generally applied to the rotating ring. The stationary ring is fitted loose for ease of assembly.
6. Spring-loaded bearings require a loose fit to ensure that the spring loading remains operational.
7. In the case of loose fits, inner and outer rings should be clamped against shoulders to minimize the possibility of non-repetitive runout.
8. Diameter and squareness tolerances for shaft and housing mounting surfaces and shoulders should be similar to those for the bearing bore and O.D. The surface finish and hardness of mating components should be suitable for prolonged use, to avoid deterioration of fits during operation.
9. Proper press-fitting techniques must be used to prevent damage during assembly. Mounting forces must never be transmitted through the balls from one ring to the other. Thus, if the inner ring is being press fitted, force must be applied directly to the inner ring.
10. When a more precise fit is desired, bearings can be obtained that are calibrated into narrower bore and O.D. tolerance groups. These can be matched to similarly calibrated shafts and housings to cut the fit tolerance range by 50% or more.
11. Mounting bearings directly in soft non-ferrous alloy housings is considered poor practice unless loads are very light and temperatures are normal and steady — not subject to wide extremes. When temperatures vary drastically, as in aircraft applications, where aluminum is a common structural material, steel housing liners should be used to resist the effects of excessive thermal contraction or expansion upon bearing fits. Such liners should be carefully machined to the required size and tolerance while in place in the housing, to minimize possibility of runout errors.

Other problems associated with non-ferrous alloys are galling during assembly and “pounding out” of bearing seats. Any questions that arise in unusual mounting situations should be discussed with the Barden Product Engineering Department.
12. For a more secure mounting of a bearing on a shaft or in a housing, clamping plates are considered superior to threaded nuts or collars. Plates are easily secured with separate screws.

When used with shafts and housings that are not shouldered, threaded nuts or collars can misalign bearings. Care must be taken to assure that threaded members are machined square to clamping surfaces. For high-speed precision applications, it may be necessary to custom scrape the contact faces of clamping nuts. In all cases, the clamping forces developed should not be capable of distorting the mating parts.

Shaft and Housing Size Determination

The fits listed in Tables 5 and 6 (pages 33 and 34) apply to normal operating temperatures and are based on average O.D. and bore sizes. The size and tolerance of the shaft or housing for a particular application can be readily computed by working back from the resulting fit, as shown in the example. Note that the total fit tolerance is always the sum of the bearing bore or O.D. tolerance plus the mating shaft or housing tolerance.
